## Abstract

The present invention is an interface between a piece of 1 baggage and a preconcentrator. The baggage-preconcentrator 2 interface is able be secured to the opening in the baggage, such 3 as an opening created by a zipper. The baggage-preconcentrator 4 interface provides a convenient entry point from which to 5 extract air from the interior of baggage. The shape of such 6 interface corresponds to that of the preconcentrator, which 7 collects constituents of air. The preconcentrator is inserted into the baggage-preconcentrator interface and an air sample is 9 extracted from the interior of the baggage and through both the 10 interface and the preconcentrator. As the air is extracted, the 11 constituents of air collect in the preconcentrator. After 12 collecting the constituents, the preconcentrator is inserted 13 into a testing unit capable of detecting trace amounts of 14 explosives, such as an ion trap mobility spectrometer. 15 testing unit analyzes the constituents and determines whether 16 any of them are explosive. 17
